Points to remember:

- Python programming language has four collections of data types such as List, Tuple, Set and Dictionary.
- A list is known as a "sequence data type". Each value of a list is called as element.
- The elements of list should be specified within square brackets.
- Each element has a unique value called index number begins with zero.
- Python allows positive and negative values as index.
- Loops are used access all elements from a list.
- The "for" loop is a suitable loop to access all the elements one by one.
- The append ( ), extend ( ) and insert ( ) functions are used to include more elements in a List.
- The del, remove ( ) and pop ( ) are used to delete elements from a list.
- The range ( ) function is used to generate a series of values.
- Tuples consists of a number of values separated by comma and enclosed within parentheses.
- Iterating tuples is faster than list.
- The tuple ( ) function is also used to create Tuples from a list.
- Creating a Tuple with one element is called "Singleton" tuple.
- A Set is a mutable and an unordered collection of elements without duplicates.
- A set is created by placing all the elements separated by comma within a pair of curly brackets.
- A dictionary is a mixed collection of elements.

Hands on Experience

1. Write a program to remove duplicates from a list.
2. Write a program that prints the maximum value in a Tuple.
3. Write a program that finds the sum of all the numbers in a Tuples using while loop.
4. Write a program that finds sum of all even numbers in a list.
