General format of __init__ method (Constructor function)

def __init__(self, [args ……..]):

<statements>

Example : Program to illustrate Constructor

```
class Sample:
        def __init__(self, num):
                print("Constructor of class Sample...")
                self.num=num
                print("The value is :", num)
S=Sample(10)
```

The above class "Sample", has only a constructor with one argument named as num. When the constructor gets executed, first the print statement, prints the "Constructor of class Sample….", then, the passing value to the constructor is assigned to self.num and finally it prints the value passed along with the given string.

The above constructor gets executed automatically, when an object **S** is created with actual parameter 10. Thus, the Python display the following output.

Constructor of class Sample...

The value is : 10

Class variable defined within constructor keep count of number of objects created with the class.

Example : Program to illustrate class variable to keep count of number of objects created.

```
class Sample:
        num=0
        def __init__(self, var):
                Sample.num+=1
                self.var=var
                print("The object value is = ", var)
                print("The count of object created = ", Sample.num)

S1=Sample(15)
S2=Sample(35)
S3=Sample(45)
```
