
13.7.1 Creating A New Normal CSV File

When you have a set of data that you would like to store inside a CSV file, it's time to do the opposite and use the write function.

The csv.writer() method returns a writer object which converts the user's data into delimited strings on the given file-like object. The writerow() method writes a row of data into the specified file.

The syntax for csv.writer() is

```
csv.writer(fileobject,delimiter,fmtparams)
```

where

fileobject :-	passes the path and the mode of the file
delimiter :-	an optional parameter containing the standard dilects like , | etc can be omitted
fmtparams :	optional parameter which help to override the default values of the dialects like skipinitialspace,quoting etc. can be omitted

You can **create** a normal CSV file using writer() method of csv module having default delimiter comma (,)

Here's an example.

The following Python program converts a List of data to a CSV file called "Pupil.csv" that uses, (comma) as a value separator.
