Points to remember:

- A CSV file is a human readable text file where each line has a number of fields, separated by commas or some other delimiter
- Excel is a binary file whereas CSV format is a plain text format
- The two ways to read a CSV file are using csv.reader() function and using DictReader class.
- The default mode of csv file in reading and writing is text mode
- Binary mode can be be used when dealing with non-text files like image or exe files.
- Python has a garbage collector to clean up unreferenced objects
- close() method will free up the resources that were tied with the file
- By default CSV files should open automatically in Excel
- The CSV library contains objects and other code to read, write, and process data from and to CSV files.
- "skipinitialspace" is used for removing whitespaces after the delimiter
- To sort by more than one column operator.itemgetter() can be used
- DictReader() class of csv module creates an object which maps data to a dictionary
- CSV file having custom delimiter is read with the help of csv.register_dialect().
- To sort by more than one column itemgetter() with multiple indices is used.
- csv.reader and csv.writer work with list/tuple, while csv.DictReader and csv.DictWriter work with dictionary .
- csv.DictReader and csv.DictWriter take additional argument fieldnames that are used as dictionary keys.
- The function dict() is used to print the data in dictionary format without order.
- The csv.writer() method returns a writer object which converts the user's data into delimited strings.
- The writerow() method writes one row at a time. Writerows() method is used to write all the data at once
- Adding a new row at the end of the file is called appending a row.
