```
import sqlite3
connection = sqlite3.connect("Academy.db")
cursor = connection.cursor()
cursor.execute("SELECT DISTINCT (Grade) FROM student where gender='M'")
result = cursor.fetchall()
print(*result,sep="\n")
```

OUTPUT

```
('B',)
('A',)
('C',)
('D',)
```

15.4.2.3 SQL Group By Clause

The SELECT statement can be used along with GROUP BY clause. The GROUP BY clause groups records into summary rows. It returns one records for each group. It is often used with aggregate functions (COUNT, MAX, MIN, SUM, AVG) to group the result-set by one or more columns. The following example count the number of male and female from the student table and display the result.

Example 15.4.2.3 -1

```
import sqlite3
connection = sqlite3.connect("Academy.db")
cursor = connection.cursor()
cursor.execute("SELECT gender,count(gender) FROM student Group BY gender")
result = cursor.fetchall()
print(*result,sep="\n")
```

OUTPUT

```
('F', 2)
('M', 5)
```

15.4.2.4 SQL ORDER BY Clause

The ORDER BY Clause can be used along with the SELECT statement to sort the data of specific fields in an ordered way. It is used to sort the result-set in ascending or descending order. In this example name and Rollno of the students are displayed in alphabetical order of names
