15.11 Using Multiple Table for Querying

Python allows to query more than one table by joining them. In the following example a new table called "Appointments" which contain the details of students Rollno, Duty, Age is created. The tables "student" and "Appointments" are joined and displayed the result with the column headings.

Example 15.11-1

```
import sqlite3
connection = sqlite3.connect("Academy.db")
cursor = connection.cursor()
cursor.execute("""DROP TABLE Appointment;""")
sql_command = """
CREATE TABLE Appointment(rollnointprimarkey,Dutyvarchar(10),age int)"""
cursor.execute(sql_command)
sql_command = """INSERT INTO Appointment (Rollno,Duty ,age )
        VALUES ("1", "Prefect", "17");"""
cursor.execute(sql_command)
sql_command = """INSERT INTO Appointment (Rollno, Duty, age)
        VALUES ("2", "Secretary", "16");"""
cursor.execute(sql_command)
#  never forget this, if you want the changes to be saved:
connection.commit()
cursor.execute ("SELECT student.rollno,student.sname,
        Appointment.Duty, Appointment.Age FROM student,Appointment
        where student.rollno=Appointment.rollno")
#print (cursor.description) to display the field names of the table
co = [i[0] for i in cursor.description]
print(co)
#  Field informations can be read from cursor.description.
result = cursor.fetchall()
for r in result:
        print(r)
```

OUTPUT

```
['Rollno', 'Sname', 'Duty', 'age']
(1, 'Akshay', 'Prefect', 17)
(2, 'Aravind', 'Secretary', 16)
```

Note

cursor. description contain the details of each column headings .It will be stored as a tuple and the first one that is 0(zero) index refers to the column name. From index 1 onwards the values of the column(Records) are refered. Using this command you can display the table's Field names.
