5.4 Input and Output Functions

A program needs to interact with the user to accomplish the desired task; this can be achieved using **Input-Output functions**. The **input()** function helps to enter data at run time by the user and the output function **print()** is used to display the result of the program on the screen after execution.

5.4.1 The print() function

In Python, the **print()** function is used to display result on the screen. The syntax for **print()** is as follows:

Example

```
print ("string to be displayed as output " )
print (variable )
print ("String to be displayed as output ", variable)
print ("String1 ", variable, "String 2", variable, "String 3" ……)
```

Example

```
>>> print ("Welcome to Python Programming")
        Welcome to Python Programming
>>> x = 5
>>> y = 6
>>> z = x + y
>>> print (z)
        11
>>> print ("The sum = ", z)
        The sum = 11
>>> print ("The sum of ", x, " and ", y, " is ", z)
        The sum of 5 and 6 is 11
```

The **print ( )** evaluates the expression before printing it on the monitor. The print () displays an entire statement which is specified within print ( ). **Comma (,)** is used as a separator in **print ( )** to print more than one item.

5.4.2 input() function

In Python, **input( )** function is used to accept data as input at run time. The syntax for **input()** function is,

```
Variable = input ("prompt string")
```
