
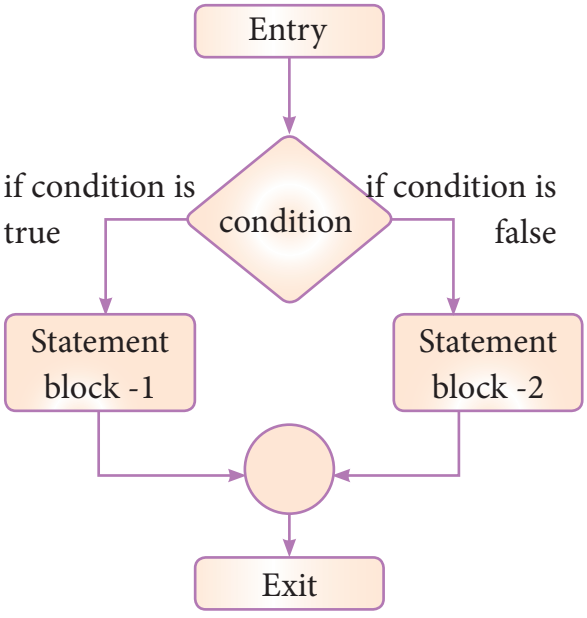

Fig. 6.1 if..else statement execution

if..else statement thus provides two possibilities and the condition determines which BLOCK is to be executed.

Example 6.3: #Program to check if the accepted number odd or even

```
a = int(input("Enter any number :"))
if a%2==0:
        print (a, " is an even number")
else:
        print (a, " is an odd number")
```

Output 1:

```
Enter any number :56
56  is an even number
```

Output 2:

```
Enter any number :67
67  is an odd number
```

An alternate method to rewrite the above program is also available in Python. The complete **if..else** can also written as:

Syntax:

variable = variable1 if condition else variable 2
