Note

pass statement is generally used as a placeholder. When we have a loop or function that is to be implemented in the future and not now, we cannot develop such functions or loops with empty body segment because the interpreter would raise an error. So, to avoid this we can use pass statement to construct a body that does nothing.

Example 6.18: Program to illustrate the use of pass statement in for loop

```
for val in "Computer":
        pass
print ("End of the loop, loop structure will be built in future")
```

Output:

End of the loop, loop structure will be built in future.

Points to remember:

- Programs consists of statements which are executed in sequence, to alter the flow we use control statements.
- A program statement that causes a jump of control from one part of the program to another is called control structure or control statement.
- Three types of flow of control are
  - o Sequencing
  - o Branching or Alternative
  - o Iteration
- In Python, branching is done using various forms of 'if' structures.
- Indentation plays a vital role in Python programming, it is the indentation that group statements no need to use {}.
- Python Interpreter will throw error for all indentation errors.
- To accept input at runtime, earlier versions of Python supported raw_input(), latest versions support input().
- print() supports the use of escape sequence to format the output to the user's choice.
- range() is used to supply a range of values in for loop.
- break, continue, pass act as jump statements in Python.
- pass statement is a null statement, it is generally used as a place holder.
