callable from views invoked by the store controller, you could define the following module in the `store_helper.rb` file in the `app/helpers` directory:

```
module StoreHelper
  def capitalize_words(string)
    string.split(" ").map {|word| word.capitalize}.join(" ")
  end
end
```

One module that's part of the standard library of Ruby deserves special mention, given its usage in Rails: YAML.

YAML

YAML[37] is a recursive acronym that stands for YAML Ain't Markup Language. In the context of Rails, YAML is used as a convenient way to define the configuration of things such as databases, test data, and translations. Here's an example:

```
development:
  adapter: sqlite3
  database: storage/development.sqlite3
  pool: 5
  timeout: 5000
```

In YAML, indentation is important, so this defines `development` as having a set of four key-value pairs, separated by colons. While YAML is one way to represent data, particularly when interacting with humans, Ruby provides a more general way for representing data for use by applications.
