The generator creates a bunch of files. The one we're interested in first is the *migration* one, namely, `20250420000001_create_products.rb`.

A migration represents a change we either want to make to a database as a whole or to the data contained within the database, and it's expressed in a source file in database-independent terms. These changes can update both the database schema and the data in the database tables. We apply these migrations to update our database, and we can unapply them to roll our database back. We have a whole section on migrations starting in Chapter 23, *Migrations*. For now, we'll just use them without too much more comment.

The migration has a UTC-based timestamp prefix (`20250420000001`), a name (`create_products`), and a file extension (`rb`, because it's Ruby code).

The timestamp prefix that you see will be different. In fact, the timestamps used in this book are clearly fictitious. Typically, your timestamps won't be consecutive; instead, they'll reflect the time the migration was created.

Applying the Migration

Although we've already told Rails about the basic data types of each property, let's refine the definition of the price to have eight digits of significance and two digits after the decimal point:

rails80/depot_a/db/migrate/20250420000001_create_products.rb

```
class CreateProducts < ActiveRecord::Migration[8.0]
  def change
    create_table :products do |t|
      t.string :title
      t.text :description
»     t.decimal :price, precision: 8, scale: 2

      t.timestamps
    end
  end
```
