the large number of connections that Rails can generate.

Thruster serves three purposes:

- It can serve static files quickly. It does this by making direct use of operating system functionality and implementing compression.
- It serves as an HTTP/2 proxy. Puma implements HTTP 1.1 and Puma's threads can only handle one request at a time. HTTP 2 allows clients to make multiple concurrent requests that are multiplexed, which is a fancy term for saying that responses can come back in any order.
- It can provide certificate management. This is used in single-machine Kamal deployments to provide SSL.

Orchestrate the Deployment

To run this image, we'll need to associate various paths on our machine with paths in the container. We'll also need to set up a network so that the web service can communicate with the database service. And we'll need to pass in the master key that we created earlier. We can do all this on the command line, but it's easier to use a file to orchestrate the deployment. We can do that all by creating a docker-compose.yml:

rails80/depot_td/docker-compose.yml

```
services:
  web:
    build: .
    volumes:
      - ./log:/rails/log
      - ./storage:/rails/storage
    ports:
      - "3000:3000"
    secrets:
      - source: master_key
        target: /rails/config/master.key
```
