We get started by editing our credentials:

```
$ EDITOR='code --wait' bin/rails credentials:edit
```

Feel free to replace the editor with vim or another editor of your choice.

You'll see that Rails has already defined one credential that's used to encrypt cookies, which is how Rails implements sessions such as the one used to track a user's cart. Leave that credential alone, and add another one to the file:

```
dave_password: secret
```

When you save the file, Rails will update config/credentials.yml.enc using the master key defined in config/master.key. The encoded file can be checked into version control and shared publicly. The key, however, needs to be kept private.

Now that we have a credential defined, let's make use of it by adding the following to db/seeds.rb:

rails80/depot_td/db/seeds.rb

```
User.create! name: 'dave',
  password: Rails.application.credentials.dave_password
```

So far, we've defined a credential and made use of it. The one task remaining is to set things up to deploy the master key at runtime. The following lines in docker-compose.yml take care of this:

rails80/depot_td/docker-compose.yml

```
services:
  web:
    secrets:
      - source: master_key
        target: /rails/config/master.key

secrets:
```
