When done, you'll end up with a rather opaque registry password that you'll need later.

Password Manager (Optional but Highly Recommended)

A password manager is a tool that stores your passwords in an encrypted form. If you're working as a team, a password manager can be used to share secrets.

Password managers supported by Kamal are 1Password[108] LastPass,[109] Bitwarden,[110] AWS Secrets Manager,[111] and Doppler.[112] Plan for $2 to $10/user/month, unless you decide to self-host, which is an option with Bitwarden.[113]

It's not recommended, but you can directly put your passwords into `.kamal/secrets`, just be sure to add this file to your `.gitignore` and `.dockerignore` files.

Builder (Optional)

Kamal can use Docker to build your images locally, but there are at least two good reasons why you wouldn't want to do so:

- If you're developing on ARM64 (like Apple Silicon), but you want to deploy on AMD64 (x86 64-bit), the build can be quite slow[114] and buggy.[115]

- If you have an asymmetric network connection (where downloads are faster than uploads), you may benefit from a configuration where you only upload your changed source to another server, where that server is responsible for uploading the considerably larger resulting Docker image.

A builder is just a host you have ssh access to that's running Docker—preferably running the target instruction set architecture. You already have
