These controllers interacted with the models in a number of ways, from finding and fetching data and putting it into instance variables to updating models and saving data entered via forms. When done, we either redirected to another action or rendered a view.

We limited the set of permitted parameters on the line item controller.

We created callback actions that were run before selected actions to find the cart, set the language, and authorize requests. We placed logic common to a number of controllers into a concern—namely, the `CurrentCart` module.

We managed sessions, keeping track of the logged-in user (for administrators) and carts (for customers). We kept track of the current locale used for internationalization of our output. We captured errors, logged them, and informed the user via notices.

We employed fragment caching on the storefront.

We also sent confirmation emails on receipt of an order.

Configuration

Conventions keep to a minimum the amount of configuration required for a Rails application, but we did do a bit of customization.

We modified our database configuration to use PostgreSQL in production.

We defined routes for our resources, admin and session controllers, and the *root* of our website—namely, our storefront.

We created an initializer for i18n purposes and updated the locales information for both English (`en`) and Spanish (`es`).

We created seed data for our database.
