just trace lines; they also contain timing statistics, cache information, and expansions of the database statements executed.

Which file is used depends on the environment in which your application is running (and we'll have more to say about environments when we talk about the `config` directory in *A Place for Configuration*).

A Place for Static Web Pages

The `public` directory is the external face of your application. The web server takes this directory as the base of the application. In here you place *static* (in other words, unchanging) files, generally related to the running of the server.

A Place for Script Wrappers

If you find it helpful to write scripts that are launched from the command line and perform various maintenance tasks for your application, the `bin` directory is the place to put wrappers that call those scripts.

This directory also holds the Rails script. This is the script that's run when you run the `rails` command from the command line. The first argument you pass to that script determines the function Rails will perform:

`console`
: Allows you to interact with your Rails application methods.

`dbconsole`
: Allows you to directly interact with your database via the command line.

`destroy`
: Removes autogenerated files created by `generate`.

`generate`
: A code generator. Out of the box, it will create controllers, mailers, models, scaffolds, and web services. Run `generate` with no arguments
