- The corresponding database table will be called `line_items`. That's the class name, converted to lowercase, with underscores between the words, and pluralized.

- Rails would also know to look for the class definition in a file called `line_item.rb` (in the `app/models` directory).

Rails controllers have additional naming conventions. If our application has a store controller, then the following happens:

- Rails assumes the class is called `StoreController` and that it's in a file named `store_controller.rb` in the `app/controllers` directory.

- Rails also looks for a helper module named `StoreHelper` in the file `store_helper.rb` located in the `app/helpers` directory.

- It will look for view templates for this controller in the `app/views/store` directory.

- It will by default take the output of these views and wrap them in the layout template contained in the file `store.html.erb` or `store.xml.erb` in the directory `app/views/layouts`.

All these conventions are shown in the following tables.

Model Naming	
Table	line_items
File	app/models/line_item.rb
Class	LineItem

Controller Naming	
URL	http://../store/list
File	app/controllers/store_controller.rb
