- `host_with_port`, which is a `host:port` string for the request.
- `port_string`, which is a `:port` string for the request if the port isn't the default port (80 for HTTP, 443 for HTTPS).
- `ssl?`, which is `true` if this is an SSL request; in other words, the request was made with the HTTPS protocol.
- `remote_ip`, which returns the remote IP address as a string. The string may have more than one address in it if the client is behind a proxy.
- `env`, the environment of the request. You can use this to access values set by the browser, such as this:

```
request.env['HTTP_ACCEPT_LANGUAGE']
```

- `accepts`, which is an array with `Mime::Type` objects that represent the MIME types in the `Accept` header.
- `format`, which is computed based on the value of the `Accept` header, with `Mime[:HTML]` as a fallback.
- `content_type`, which is the MIME type for the request. This is useful for `put` and `post` requests.
- `headers`, which is the complete set of HTTP headers.
- `body`, which is the request body as an I/O stream.
- `content_length`, which is the number of bytes purported to be in the body.

Rails leverages a gem named Rack to provide much of this functionality. See the documentation of `Rack::Request` for full details.
