```
/tmp/storage/*
!/tmp/storage/
!/tmp/storage/.keep

/public/assets

# Ignore master key for decrypting credentials and more.
/config/master.key

/app/assets/builds/*
!/app/assets/builds/.keep
```

Note that because this filename begins with a dot, Unix-based operating systems won't show it by default in directory listings. Use `ls -a` to see it.

At this point, you're fully configured. The only tasks that remain are to add all the files and commit them with a commit message (note that Rails has initialized our repository with `git init` already):

```
depot> git add .
depot> git commit -m "Depot Scaffold"
```

Being fully configured may not seem very exciting, but it does mean you're free to experiment. If you overwrite or delete a file that you didn't mean to, you can always get back to this point by issuing a single command:

```
depot> git checkout .
```
