In 2011, the Internet Engineering Task Force (IETF) published a Standards Track document describing a two-way WebSocket protocol.[57] Action Cable provides both a client-side JavaScript framework and a server-side Ruby framework that together seamlessly integrate the WebSocket protocol into the rest of your Rails application. This enables features like real-time updates to be easily added to your Rails application in a manner that performs well and is scalable.

Making use of Action Cable is a three-step process: create a channel, broadcast some data, and receive the data. And by now, it should be no surprise that Rails has a generator that does most of the work (for two out of the three steps, anyway):

```
depot> bin/rails generate channel products
     invoke  test_unit
     create    test/channels/products_channel_test.rb
  identical  app/channels/application_cable/channel.rb
  identical  app/channels/application_cable/connection.rb
     create  app/channels/products_channel.rb
     create  app/javascript/channels/index.js
     create  app/javascript/channels/consumer.js
     append  app/javascript/application.js
     append  config/importmap.rb
     create  app/javascript/channels/products_channel.js
       gsub  app/javascript/channels/products_channel.js
     append  app/javascript/channels/index.js
```

The way to create a channel is by updating the file created in the **app/channels/** directory:

rails7/depot_o/app/channels/products_channel.rb

```
class ProductsChannel < ApplicationCable::Channel
  def subscribed
»   stream_from "products"
  end

  def unsubscribed
    # Any cleanup needed when channel is unsubscribed
  end
end
```
