

It's not pretty, but it'll work for now. Next, we need to add the ability to write a response. If we were OK with plain text, we would make a new attribute on `SupportRequest` to hold the response, then wire up a form to write it, just like we've done several times. With rich text, it works a bit differently.

Action Text stores the rich text in its own table outside of the model's. In our `SupportRequest` model, we'll tell Rails that we have a rich-text field that we want Action Text to manage by using the `has_rich_text` method, like so:

rails7/depot_tc/app/models/support_request.rb

```
class SupportRequest < ApplicationRecord

  belongs_to :order, optional: true

    has_rich_text :response
end
```

This method (and the rest of Action Text) won't work without some setup, which we can do with the Rake task `action_text:install`:

```
> bin/rails action_text:install
      append  app/javascript/application.js
      append  config/importmap.rb
```
