Rails provided basic tests for all our scaffolded controllers, which we maintained as we made changes. We added tests along the way for things such as Ajax and ensuring that a cart has items before we create an order.

We used fixtures to provide test data to fuel our tests.

We created an integration test to test an end-to-end scenario involving a user adding product to a cart, entering an order, and receiving a confirmation email.

Deployment

We deployed our application to a production-quality web server (nginx) using a production-quality database server (PostGreSQL). Along the way, we installed and configured Phusion Passenger to run our application, Bundler to track dependencies, and Git to configuration manage our code. Docker compose was employed to orchestrate updating the deployed web server in production from our development machine.

We made use of `test` and `production` environments to prevent our experimentation during development from affecting production. Our development environment made use of the lightweight SQLite database server and web server, Puma. Our tests were run in a controlled environment with test data provided by fixtures.
