In the database, however, the name and email address are obscured by our industrial-strength encryption:

```
depot> sqlite3 -line db/development.sqlite3 "select * from orders"
     id = 1
user_id =
   name = Dbwf Tipnbt
address = 123 The Street
  email = ebwf@fybnqmf.dpn
```

Callbacks are a fine technique, but they can sometimes result in a model class taking on responsibilities that aren't really related to the nature of the model. For example, in *Participating in the Monitoring Process*, we created a callback that generated a log message when an order was created. That functionality isn't really part of the basic `Order` class—we put it there because that's where the callback executed.

When used in moderation, such an approach doesn't lead to significant problems. If, however, you find yourself repeating code, consider using concerns[101] instead.
