- `ssl?`, which is `true` if this is an SSL request; in other words, the request was made with the HTTPS protocol.
- `remote_ip`, which returns the remote IP address as a string. The string may have more than one address in it if the client is behind a proxy.
- `env`, the environment of the request. You can use this to access values set by the browser, such as this:

```
request.env['HTTP_ACCEPT_LANGUAGE']
```

- `accepts`, which is an array with `Mime::Type` objects that represent the MIME types in the `Accept` header.
- `format`, which is computed based on the value of the `Accept` header, with `Mime[:HTML]` as a fallback.
- `content_type`, which is the MIME type for the request. This is useful for `put` and `post` requests.
- `headers`, which is the complete set of HTTP headers.
- `body`, which is the request body as an I/O stream.
- `content_length`, which is the number of bytes purported to be in the body.

Rails leverages a gem named Rack to provide much of this functionality. See the documentation of `Rack::Request` for full details.

response

The response object, filled in during the handling of the request. Normally, this object is managed for you by Rails. As we'll see when we look at callbacks in *Callbacks*, we sometimes access the internals for specialized processing.
