```
 :@_action_name, :@_response_body,
:@marked_for_same_origin_verification,
 :@_config, :@articles]
```

```
(byebug) help var
  [v]ar <subcommand>
  Shows variables and its values
  var all      -- Shows local, global and instance variables of self.
  var args     -- Information about arguments of the current scope
```

And then ask again for the instance_variables:

Now @articles is included in the instance variables, because the line defining it was executed.
You can also step into irb mode with the command irb (of course!). This will start an irb session within the

context you invoked it.

The var method is the most convenient way to show variables and their values. Let's have byebug help us with it.

```
  var const    -- Shows constants of an object.
  var global   -- Shows global variables.
  var instance -- Shows instance variables of self or a specific
object.
  var local    -- Shows local variables in current scope.
(byebug) help var
  [v]ar <subcommand>
  Shows variables and its values
var all
var args
var const
var global
var instance -- Shows instance variables of self or a specific
-- Shows local, global and instance variables of self.
-- Information about arguments of the current scope
-- Shows constants of an object.
-- Shows global variables.
```
