10.3.3 Mobile Networks

Mobile network is the network connecting devices without cable (wireless). Mobile computers, such as laptop, tablet, and hand held computers, were fastest growing segments. At land areas network was distributed as cells, each will be served by single – location transceiver, but generally three cell sites or a base transceiver station. This base station provides the cell with network coverage and other features that can be utilized for transmission of voice, data and other content as well. Joining together all radio coverage is called as wide geographical area. This portable transceivers used to communicate with one another with fixed transceivers and moving via more than one cell during transmission. For example mobiles, tablets, pagers, laptops, engaged with mobile broadband just like modems etc. Refer Figure 10.6

Features of Mobile Networks

- Less consumption of power is used by mobile devices compared to a single transmitter or satellite since the cell towers are closer.
- Huge capacity than a large transmitter, at single frequency can be used for different or many links as long as they are in different in cells.
- As mobile phones are now heavily used for data communication, the mobile network traffic is fully busy.

Mobile phone converts voice, text, multi-media message or data calls into Radio-frequencies (RF). Mobile phone base stations transmit and receive these RF signals and connects callers to other phones and other network.

Private cellular networks can be used at various locations like research, large organizations and small industries.

After the reach of mobile and access to Internet work progress faster. People can be in touch with others even while traveling. Important informations can be received any time without much problems. Searching important topics, checking mail, watching progress of company can be done easily sitting at one place. Adequate computer knowledge is sufficient to access Internet via mobile network.
