Russian fighters (e.g., Su-57), providing strike, reconnaissance, and electronic-warfare support.

Technically, the Hunter-B emphasizes stealth, payload flexibility, and cooperative autonomy: internal weapon bays preserve low observability while modular sensor suites (EO/IR, radar, EW pods) and data links enable multi-sensor fusion and real-time sharing with manned aircraft. The demonstrator has reportedly been used to evaluate autonomous flight control, low-observable construction techniques, and integration with fighter-based command networks. Its power plant is a single turbofan sited to reduce infrared signature; its flight envelope targets medium-altitude, long-endurance missions with the ability to penetrate contested airspace under the escort of manned assets.

Key features and roles (book-style summary):

- Blended flying-wing, low-observable airframe for reduced RCS and improved aerodynamics.
- Internal bays for weapons and sensors to maintain stealth during strike missions.
- Onboard sensor fusion (EO/IR, possible AESA/SAR radar options) and EW capabilities for multi-role operations.
- Designed for cooperative operations with manned fighters (manned–unmanned teaming) and autonomous or semi-autonomous sorties.
- Focus on testing autonomy, stealth manufacturing techniques, and integration with existing tactical networks.

Representative specifications (publicly reported / indicative):

- *Type*: Stealth UCAV demonstrator
- *Developer*: Sukhoi/United Aircraft Corporation (Russia)
