Period/year	Concept/ development	Inventor/ developer	Technological principle	Significance/ contribution
				to practical drone systems.

The period between 1898 and 1945 marked the establishment of key technological principles such as wireless communication, mechanical automation, and radio-guided flight. Early innovators, including Nikola Tesla, A. M. Low, and Charles Kettering, introduced the fundamental concepts of remote control and autonomous operation. The Queen Bee (1935) and Radioplane OQ-2 (1939) represent milestones where UAVs transitioned from experimental devices to practical military tools.

2.3 Historical Development

The historical development of first-generation drones reflects the pioneering efforts that transformed the concept of unmanned flight from theoretical experimentation into practical aerial systems. This period, spanning from the early 20th century to the late 1930s, established the foundation for modern unmanned aerial vehicles (UAVs) through progressive advancements in radio control, mechanical design, and propulsion technologies.

The origins of UAV development can be traced back to early 20th-century wartime experimentation, particularly during World War I, when engineers and scientists sought to create pilotless aircraft to reduce risks to human pilots during reconnaissance and combat operations. The British engineer A. M. Low played a pivotal role with his creation of the Aerial Target (1916), one of the first radio-controlled aircraft designed to intercept enemy zeppelins. Although the technology of the time limited its success, it
