EXCEL ORDER OF OPERATIONS

The order of operations determines how calculations are performed in an Excel formula. Understanding this order is essential as it can impact the final result.

Excel has a set hierarchy for the order of operations. The tasks at the top of the hierarchy are done before those at the bottom. In Excel, tasks are done in the following order:

- **Parentheses**( ): The operations contained within parentheses are always completed before anything else.
- **Exponents**^: The next step is to compute the exponents, which include squares and cubes.
- **Multiplication** * and **Division** /: The order in which these operation are carried out is left to right.
- **Addition** + and **Subtraction** -: These operations are executed in the same sequence, from left to right.

When you are creating a formula that involves different types of operations, it is really important to use parentheses to indicate the order in which the operations should be executed. This will help ensure that the formula produces the correct result.

For example, in the formula; **=3+(4*5)**

The multiplication operation (**4*5**) will be carried out before the addition operation **3+** because multiplication and division operations have higher precedence than addition and subtraction.
