ABSOLUTE, RELATIVE, AND MIXED CELL REFERENCES IN EXCEL

Cell references are a great way to work with data in Excel since they let you create formulas and functions that are dynamic and flexible. However, Knowing the different types of cell references and how to use them is important because using the wrong t reference can lead to calculation errors.

Excel has three types of cell references: relative, absolute, and mixed. Excel formulas and functions can be faster and easier if you understand these different references.

A relative cell reference describes the cell's location relative to the reference cell. Copying a formula with a relative cell reference will automatically adjust the reference to the new location.

In the following example, you have a set of data as follows:

	A	B	C	D	E
1	**Category A**	**Stock**	**Purchase Price**	**Selling Price**	**Profit or Loss**
2	Beverages	2,000	$250.00	$300.00	
3	Condiments	4,000	$350.00	$420.00	
4					

Supposing you want to calculate each item's **Profit** or **Loss** by subtracting the **Purchase Price** from the **Selling Price**. You can use a relative cell reference to refer to your formula's **Purchase Price** and **Selling Price** columns, as illustrated below.
