

This formula multiplies the value in cell **D3** by the value in cell **F1** to calculate the commission.

Absolute cell references allow you to use a **fixed** cell reference in a formula, even when the formula is copied to other cells. This can be useful when using a constant value in a formula, such as a tax rate or commission percentage.

A **Mixed cell reference** is similar to a relative cell reference, except that it anchors the coordinates of one row or column to a specific value.

Mixed cell references can be useful when you want one cell reference to be fixed but the other to change based on the formula location.

Mixed cell references can be in two forms:

- When you copy a formula, the row stays locked while the column changes.
- The column stays locked while the row changes when you copy the formula.

For example, the illustration below is a data set with commission calculated for the percentage value in cells **E2**, and **F2** .
