AVERAGEIF FUNCTION

With Excel's AVERAGEIF function, you can calculate a range of cells' average values based on a specified condition or a single value based on a range of cells when a particular condition is met. A good application of this function would be if you have a large dataset and want to find the average value for a particular subset of data within that dataset.

AVERAGEIF has the following syntax:

AVERAGEIF(range, criteria, [average_range])

A **range** argument specifies the range of cells to which the criteria should be applied.

The **criteria** argument specifies the conditions that must be met for a cell to be included in the average.

In the **average_range argument**, specify the range of cells you wish to average.

In the absence of this argument, Excel uses the range argument.

For example, in a **Staff Out-Station Expenses** worksheet illustrated below, the **AVERAGEIF** function is used to find the average base on a Specific **ITEM**, such as **Electricity**.
