NOT FUNCTION

NOT Function is used when you want a formula to return an opposite result to a logical test. This means if the given logical test is FALSE, the formula returns TRUE; otherwise, it returns a FALSE result if the logical test is TRUE.

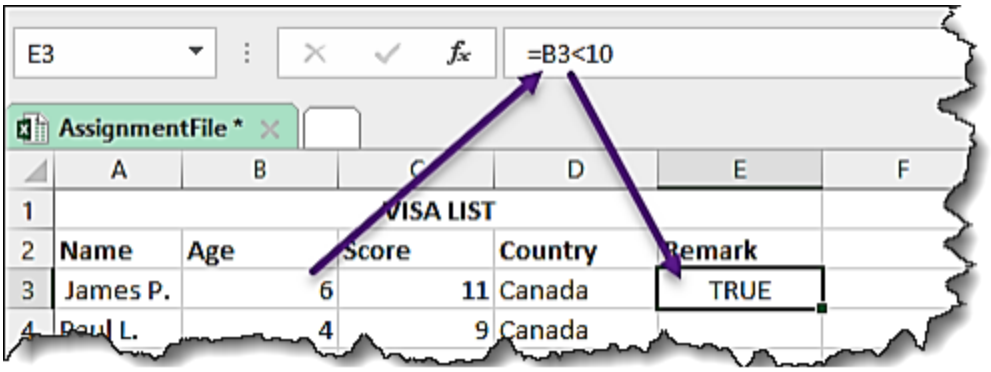

To create a more advanced formula, you can also nest the NOT function with other logical functions like IF, AND, and OR. This approach allows you to make more accurate decisions based on available data.

The **NOT** function syntax is as follows:

NOT(logical_test).

The logical_test can be any value or an expression considered as either TRUE or FALSE.

For example, if you want to check if a particular cell value is less than 10, the logical test would be **B3<10**.

To check if the value is **NOT** less than 10, you would use the NOT function like this:

=NOT(B3<10)
