For example, to check if a cell value is equal to "**Canada**" or "**US**" you can use the **OR** function like this:

=OR(**D3**="Canada", **D3**="US")

On the other hand, if you want to return a value as **FALSE** when a particular condition is not met, you can use the **FALSE** function in conjunction with the **OR** function in the following way;

=IF(OR(D3="Canada", D3="US"),"True",FALSE)

The formula in the above example returns "**True**" if the value in cell **D3** is "**Canada**" or "**US**", and FALSE if the value is not "**Canada**" or "**US**".

If you combine the **FALSE** function with the **NOT** function, it inverts the logical test and returns True if the condition is False and vice versa.

For example, to check if the value in cell **B3** is not equal to 10, the **NOT** function is used like this:

=**NOT**(**B3**=10)

Alternatively, suppose you wish to return the value in cell **B3** as **FALSE** when a particular condition is not met. In that case, you can use the **FALSE** function in combination with the **NOT** function in the following way:
