and extracts 6 characters.

Excel allows you to combine other Text functions with the MID function, such as the LEFT and the RIGHT function, to extract specific parts of a Text string.

For example, using the formula in cell **B2**:

=LEFT(A2, 8) & MID(A2, 8, 3) & RIGHT(A2, 6)

The formula would return "**Buchanan, Steven**".

When adding the MID Function with other Excel functions, Text case sensitivity is something you should note, such as the UPPER function or the LOWER Function.

For example, the LOWER or UPPER Excel function can be used in a formula when comparing "Steven" and "STEVEN" as different by converting the cell content to the same case before using the MID function. This can be useful in circumstances where the case of the text in a cell may vary, but the information contained within the text should be considered the same.

A simple example of how the LOWER function might be used in conjunction with the MID function in Excel is shown below:
