FORMS OF EXCEL LOOKUP FUNCTIONS

There are two forms of LOOKUP in Excel:

- **Vector**: The vector form searches for a value in a specified column or row.
- **Array**: The array form searches for a particular value in the first column or row of the array and retrieves a value within the exact location in the last column or row of the array.

Both forms have their syntax and method of usage.

The Vector form of the LOOKUP function in Excel has the following syntax for its four arguments:

LOOKUP(lookup_value,lookup_vector,[result_vector])

The Array form of the LOOKUP function in Excel has the following syntax for its three arguments:

LOOKUP(lookup_value, array)

The Vector form is applicable when you don't have the exact value you are looking for and need to use a nearby value to find the exact result.

The Array form is useful when looking up a value in one column and returning a result from the same row from another column.

We can look at examples to understand how to use the LOOKUP Function.

Assume you have a score sheet with the Student name, faculty, and exam score as illustrated below.
