Since the fourth argument in the formula was omitted, the formula is rather performing an approximate match. In such cases, the **VLOOKUP function** assumes the table is sorted, and it then returns the value from the previous row if it finds one that is greater than the lookup value. The correct answer should be $35,000.00, but the VLOOKUP returned $18,000.00, which is incorrect.

Therefore, it is vital to always remember to make the fourth argument either FALSE or 0 if you want to do an exact match.

Before using either the Index or Match function, sorting your data in ascending order will help give you a better result.
