type, or showcase each department’s contribution to the total revenue of the company.

In such scenarios, the most suitable charts include:

- **Pie Chart**
  This chart is useful for providing a straightforward representation of how a dataset contributes to 100%.
- **Doughnut Chart**
  The doughnut chart enables you to visualize multiple datasets, each representing a significant portion of the total data volume.
- **Column or Bar Chart**
  These charts are useful for analysing the components of a whole and how they evolve. For instance, you can track the sales trends of individual products as a percentage of total sales.

DISTRIBUTION CHARTS

Distribution charts are effective for visualizing the spread of data across a large dataset. They are particularly useful in survey-related contexts, such as presenting age-based survey results, analysing the frequency of complaints in a call centre, or illustrating the distribution of exam scores in schools.

The most appropriate charts for working with this type of data include:

- **Histogram**
  The histogram chart is ideal for showcasing the frequency distribution of values by dividing them into sections.
- **Pareto Chart**
  This chart is useful when you want to display the relative portion of each category compared to the total. It also enables you to incorporate significant factors.
- **Scatter Chart**
  As mentioned earlier, this chart is valuable for analysing the relationships between datasets and their distribution.
- **Boxer and Whisker Chart**
