into routine analysis and reporting tasks.

BROWSING BUTTON

The most common use of macros involves browsing. For instance, workbooks with many worksheets or tabs may be frustrating to browse. To simplify this process, navigation buttons can be created. For instance, clicking the “Example 1” button could automatically direct users to the “Example 1” sheet.

To create a macro to browse a sheet, follow these steps:

1. Start with the sheet you want to use as the starting point.
2. Start recording a macro.
3. During recording, click on the target sheet (the sheet you want the macro to browse to).
4. Stop recording.
5. Add a module control button on the starting point and assign the macro to the button by selecting it within the *Assign Macro* dialog box.

Excel’s hyperlink feature enables you to convert cell contents into clickable links that direct users to various locations, including other Excel workbooks, websites, or different tabs within the same workbook. While creating a hyperlink is simpler compared to setting up a macro, it’s worth noting that hyperlinks cannot be applied directly to form controls like buttons.

If you opt to use a hyperlink instead of a button, you’ll need to utilize text to indicate to users where the link will take them when clicked.

DYNAMIC REORGANIZATION OF PIVOTTABLE DATA

Another frequent application of macros is to enable users to change the file present in the PivotChart and PivotTable by simply selecting one of the buttons shown.

The macros recorded and assigned to these buttons essentially reconfigure the PivotTable to segment the data using various Pivot fields.

To perform this configuration, follow these steps:

1. Create the PivotTable and a PivotChart.
2. Start the recording of a macro.
3. Move a Pivot Field from one area of the PivotTable to another and
