will also display a Modules section.

Adding a new VBA module

When you record a macro, Excel automatically creates a VBA module to store the recorded code. The workbook that houses this module depends on where you chose to store the recorded macro, which is an option presented just before you begin recording actions.

VBA form can contain three types of code:

1. Statements: one or more informative statements can be provided to the macro, like indicating the type of output for the variables to be used or setting other options at the macro level.
2. Sub-procedures: a macro consists of a set of programming statements that perform specific actions. For instance, all registered macros are Sub-procedures.
3. Function procedures: a function is a set of programming instructions that return a single value. Conceptually, they are quite like worksheet functions, such as the SUM function.

The organization of a VBA module is strictly personal and related to one's needs: some users prefer to keep all their VBA code for an application in one module, while others prefer to split their code into several modules.

To manually add a new VBA module to a project, follow these steps:

1. In the project window, select the project name.
2. Choose the Insert option and then click on the *Module* item. Alternatively, you can right-click on the project name, choose Insert and select *Module* from the shortcut menu.
