with code windows. Recorded macros are stored in modules, and you can also write VBA code directly within these modules.

Code windows function similarly to workbook windows in Excel: you can minimize, enlarge, resize, hide, and perform other actions. To enlarge a code window, simply click the maximize button in the title bar or double-click the title bar. To restore a code window to its original size, click the restore button (the icon resembling a box).

In certain scenarios, you might find it helpful to arrange two or more code windows side by side. For instance, you may need to compare code in two different modules or copy code from one module to another.

In these cases, you can arrange the windows manually or use the following these steps: *Window > Tile Horizontally or Window > Tile Vertically*. You can quickly switch from one code window to another by pressing *Ctrl+Tab*.

INSERT VBA CODE INTO A MODULE

Before undertaking more complex operations, it's essential to enter VBA code in the VBA module. It can be entered in three ways:

1. Using Excel's macro recorder to record actions and convert them to VBA code.
2. By directly entering the code.
3. Copying code from one form and pasting it into another.

In the previous pages, we've learned how to generate code using the macro recorder. However, not all tasks can be translated into VBA by this tool. Often, it's necessary to manually input or copy code into the module from another source.

Another advantage is that inserting and editing text in a VBA module is intuitive. Users can select, copy, cut, paste, or perform many other operations similar to those in other basic Office applications.

A line of VBA code can extend for any desired length, but it may be convenient to employ the line continuation character to split longer lines of code. To do this, simply end the first line of code with a space followed by the "_" character and then continue the code in the next line.

Here is an example of a single statement split over three lines:

```
Selection.Sort Key1:=Range("A1"), _
Order1:=xlAscending, Header:=xlGuess, _
```
