Orientation:=xlTopToBottom

This statement would work the same way even if it were inserted in a single line, that is, without the line continuation characters.

Another point to note is that the VBA editor has multiple levels of undo and redo. For instance, when you delete a statement by mistake, you can use the Undo button found on the toolbar or press Ctrl+Z until the statement appears again. Simply press the Redo button to execute the changes you just undid.

ENTER A CODE MANUALLY

To manually enter VBA code, follow these steps:

1. Create a new workbook in Excel.
2. Press *Alt+F11* to activate the editor.
3. Click on the name of the new workbook in the project window and choose *Insert* and then *Module* to insert a VBA module into the project.
4. Type the following code into the form:

```
Sub RESULT_1()
If Range("B2") < 60 Then MsgBox "Exam failed!"
If Range("B2") >= 60 Then MsgBox "Compliments! Exam passed!"
End Sub
```

5. Make sure the cursor is anywhere within the typed text and press *F5* to execute the procedure. (*F5* is a shortcut for the *Run > Run User Sub/Form command*).

When you enter the mentioned code, you may notice that the editor automatically adjusts the text you type. For instance, after typing the *Sub* statement, the editor will automatically insert the *End Sub* statement. Similarly, if you forget to include a space before or after an equal sign, the editor will insert it for you.

Additionally, the editor may change the colour and capitalization of some text. These variations help keep the code organized and easy to read.

By following these steps, you've created a VBA Sub procedure, or macro. Pressing F5 will execute the code, and Excel will follow the instructions you've provided. Each statement in the code will be evaluated, and Excel will perform the actions as specified. In this case, it will report whether the exam was passed:
