to enter inventory details (product code, description, quantity available, unit price, supplier, purchase date, sale date, expiration date, and so on). Once the product data has been recorded in the worksheet, conditional formatting can be used to highlight any low stock or out of stock products.

Stock update

Excel formulas can be used to automatically update the quantities available in the worksheet.

For instance, with the formula =*Initial Quantity* + *Purchased Quantity* – *Sold Quantity* the current quantity of a given product can be calculated. Additionally, the formulas can be leveraged to calculate the total inventory value: simply multiply the unit price by the available quantity.

Minimum stock tracking

To minimize the possibility of running out of a product, a column can be inserted dedicated to the desired minimum stock for each reference. Once the minimum stock is set, conditional formatting will allow products that are below this limit to be highlighted.

This will make Excel easier to understand when new orders need to be placed. For an even more immediate message, there is the option of creating an automatic alert using a conditional formula that compares the quantity available with the minimum stock, showing a specific message when it is necessary to reorder the product.

Product	Quantity
A	49
B	345
C	678
D	35
E	435

Order and supply management

To manage orders, simply create a separate sheet in which to record order details such as supplier, order date, products ordered, price, and quantities.

Here it is useful to use formulas to keep track of quantities that have been ordered and references or quantities that still appear to be on
