- **Reorder level**
  Useful for calculating the inventory level at which a reorder needs to be placed. The formula can consider average daily consumption, reorder time, and consumption variance.
  For example: *=(Average daily consumption * Reorder Time) + safety margin* will calculate the reorder level based on these factors.

- **Average time in inventory**
  Useful for calculating the average time a product remains in inventory before it is sold.
  The formula is as follows: *Days in year / Inventory Turnover*. This indicator makes it possible to improve the performance of inventory management.

- **Inventory variation**
  Useful for calculating the variation of inventory in a specific period.
  The formula is as follows: *Closing Valuation – Opening Valuation.* This provides an indication of inventory growth or declining over time.

- **Inventory value**
  Useful for calculating total inventory value.
  The formula to use is: *Quantity * Unit Price* for each product in the inventory with the final sum of the results. This formula gives an estimate of the value of the inventory at a given time.
