is designed specifically to handle the #N/A error. The correct syntax for the formula is as follows:

***=IFNA(value, value_if_na)***

The "*value*" argument stands for the formula or expression you want to evaluate, "*value_if_na*" stands for the output you want to get in case the formula yields the error *#N/A*.
For instance, suppose you have a formula seeking a value within a table, but if that value is not found, the formula returns the error *#N/A*. In such cases, uou can use the *IFNA* function to handle the error and generate a customized message as output instead of the standard error. In this case, the formula would be:

***=IFNA(VLOOKUP(A1; B:C, 2; FALSE); "Not Found")***

Both functions serve the purpose of enhancing comprehension of errors in Excel formulas by providing values or messages.

## MATH FUNCTIONS

Many math functions can be used in Excel to perform a wide range of calculations. In this section, we will focus on the most commonly used ones.

- **SUMIF and SUMIFS Function**
  These functions are used for the conditional summation of values within a specified range of cells.
  Specifically, the SUMIF function calculates the sums of values in a range that satisfy a particular condition or criterion. The correct syntax for the formula is as follows:

***=SUMIF(range, criteria, [sum_range])***

The "*range*" argument represents the range of cells to sum, while the "*criteria*" argument stands for the conditions to be met. These conditions can include text, a numerical value, a reference to a cell, or a formula that generates either a number or text.
Finally, the "*sum_range*" argument refers to the optional range of cells to be summed if the corresponding cells in the range meet the specified criteria. If this argument is omitted, Excel will sum the cells
