For instance, to truncate the number 3.14159 to one decimal digit, you can use the following formula:

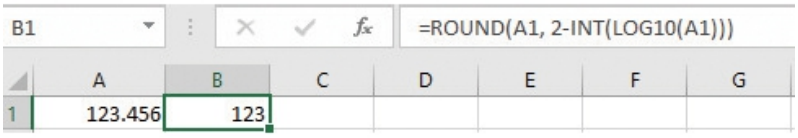

=TRUNC(3,1419; 1)

In this case, the result will be 3,1.

Although Excel lacks a dedicated function for rounding to a specified number of digits, it's feasible to accomplish this by combining the *ROUND* function and the *LOG10* function.
For instance, to round the number 123.456 to 2 significant digits, you can use the following formula:

=ROUND(123.456; 2-INT (LOG10(123.456)))

This formula enables the extraction of the integer part of the logarithm of the absolute value of the number by determining the number of digits to the left of the decimal point. Subsequently, this value is subtracted from the desired number of significant digits (2 in this case) to ascertain the number of decimal places to which the number should be rounded.

Excel then enables you to *round a value to the nearest even number*. This function can prove useful for statistical purposes, such as rounding the result of a division to an even number of decimal places. To round a number up or down to the nearest even number, the correct syntax for the formula is as follows:

=IF(MOD(number;2)=0;ROUND(number;0);ROUND(number-0,5;0)-1)

Initially, this formula verifies whether the number is even (i.e., whether it yields a remainder of 0 when divided by 2). If it is even, the formula rounds the number to 0 decimal places. If it is not even, it
