search value in the first column of the table.
Let's make an example, let's consider a table with two columns: the first column indicating "product ID" and the second column indicating "price." If our objective is to find the price for a specific product ID, such as "1001", we can use the *VLOOKUP* function as follows:

=VLOOKUP(1001, A2:B10, 2, FALSE)

In this scenario, the value to be searched is 1001, the range is A2:B10, the column number is 2 (since the price is in the second column of the table), and the match is set to FALSE (indicating we want an exact match, not an approximate one).
Excel will search for the value 1001 in the first column of the table, the "Product ID" column, and will return the corresponding value found in the second column, i.e., the "Price" column, which is 9.00 €.

- **INDEX Function**
  This function enables obtaining a value from a predefined range of cells or an array, based on the row and column coordinates given. The correct syntax for the formula is as follows:

=INDEX(array; row_num; column_num)

The "*array*" argument stands for the range of cells in which you want to search, the "*row_num*" argument stands for the number of the row from which you want to retrieve the value, and the "*column_num*" argument is an optional number indicating the column from which you want to receive the output. If this value is omitted, Excel will return the entire row specified under "*row_num*" argument.
For instance, consider a table of company sales data with columns for "*Region*," "*Product*," "*Quarter*," and "*Sales*". In this case, the *INDEX*
