product names in cells A2:A10, the following formula could be used to find the position of product “X”:

= MATCH(“X”, A2:A10, 0)

This formula will provide the position of the first occurrence of “X” in the range A2:A10. If “X” is not found, the function will return #N/A, indicating an error value.

	A	B	C	D	E	F
1	PRODUCT ID	REGION	SALES			
2	Apples	Marche	243.340			
3	Pears	Lombardia	343.393			
4	Peaches	Lazio	934.834			
5	Bananas	Emilia Romagna	389.393			
6	Plums	Veneto	423.343			
7	Oranges	Puglia	211.587			
8	Mandarins	Campania	343.444			
9	Grape	Molise	676.421			
10						
11			7			

EXAMPLE OF NESTING BETWEEN INDEX AND MATCH

The nested INDEX and MATCH functions are popular among experienced Excel users. However, many find it challenging to grasp their workings without a practical example that illustrates the benefits of using these functions together.

Let’s explore a nested function where both INDEX and MATCH are employed. Imagine we’re working with a worksheet containing two tables: the first table lists products, including identification codes and prices, while the second table focuses on orders, featuring product codes and quantities ordered by customers.

In this scenario, nesting allows the creation of a formula that, starting from the product code in a cell of the orders table, can find the corresponding price in the products table.

Here is how the worksheet would look like:
