Lobe pump

In a lobe pump, two lobes are placed inside a casing and casing and are made to rotate to pump out liquids. A lobe pump is illustrated in figure.

Lobe Pump

The case of the pump is made of cast iron. Both the lobes get rotational power separately to rotate at same speed. Both the shafts will be extending outside to receive power. They are secured properly in the case with proper packing to avoid leakage of oil.

The pump is provided with an inlet and an outlet. The gap between the lobes and the case is minimum and so the oil is pumped through the gaps from the inlet to the outlet.

Screw pump

Screws having helical grooves are used in this pump. When the screw starts rotating, the oil is allowed through the helical grooves. The action of the pump is simple and smooth and pumps out the liquid at high speed. They are used mostly in submarines.

8.12 Hydraulic motor

It is a device used to transform hydraulic energy into mechanical energy. Any hydraulic motor can be used as a hydraulic pump. But a few types of pumps only can be used as hydraulic motor.

The capacity of the hydraulic motor depends upon the quantity of the hydraulic energy that it receives and its mechanical efficiency.

Hydraulic gear

The combination of hydraulic pump and hydraulic motor can be called as hydraulic gear. It is equivalent to a gear box in a mechanical drive.

Types of hydraulic motor

The different types of hydraulic motors are

1. Rotary motor
2. Reciprocating motor
3. Constant speed motor
4. Variable speed motor

As in hydraulic pumps, there are different types of hydraulic motors like gear motor, vane motors, radial reciprocating motor, linear reciprocating motor etc.,
