Elixir provides a built-in testing framework called ExUnit. It's a great testing library that has an intentionally limited number of features and assertions. Despite being a small library, ExUnit is powerful and expressive—largely due to its support for pattern matching. ExUnit verifies that asserted patterns match correctly. And if a pattern doesn't match, ExUnit highlights what specifically was different between the left and right sides.

ExUnit tests are specified by using the `ExUnit.Case` module. This brings in all of the testing functions so you have complete access to test your code. Otherwise, ExUnit test modules are just plain modules. You can create private functions and module attributes to create clean tests. Plus, you can use test-only modules like testing factories to streamline your tests.

Phoenix provides the `DataCase` and `ConnCase` modules to enable the testing of queries and endpoints. Other libraries, like Oban, provide their own testing helpers to make it easy to test your application code. Sometimes your tests get complex though, such as when testing external API requests. Bypass solves testing external API requests by spinning up short-lived HTTP servers that are used by your test suite.

That's it for our application! But there's still one more chapter. We'll cover developing and advanced libraries in Elixir that show a strong future for the Elixir ecosystem.
